A simplified process flow diagram for the conventional naphtha steam-cracking process is shown in Fig. 1(a). As the first step, preheated naphtha is thermally cracked in the presence of steam. Since naphtha cracking is equilibrium limited and tends to form coke, steam is used as a diluent to enhance naphtha conversion and inhibit coke formation.

Pygas is a naphtha-range product with high aromatics content used either for gasoline blending or as a feedstock for a BTX extraction unit. Pyrolysis gasoline is produced in an ethylene plant that processes naphtha, butane or gasoil. Pyrolosis gasoline or pygas (C5+ cut) is a liquid by-product derived from steam cracking of various hydrocarbon feedstocks in olefin plants.

production are naphtha and natural gas (ethane, propane, butane, etc.). The first step in the production of ethylene is to take the feedstock and crack it into ethylene and other various products in a furnace. This process is called pyrolysis. Pyrolysis is the thermal cracking of petroleum hydrocarbons with steam, also called steam cracking.

Steam cracker units are facilities in which a feedstock such as naphtha, liquefied petroleum gas (LPG), ethane, propane or butane is thermally cracked through the use of steam in a bank of pyrolysis furnaces to produce lighter hydrocarbons. The products obtained depend on the composition of the feed, the hydrocarbon-to-steam ratio,

A typical process flow diagram (PFD) of such a vacuum distillation column is presented. Light vacuum gas Oil is sent to a hydrotreater and then to a 'catalytic cracking' unit to obtain smaller chain hydrocarbons. Heavy vacuum gas oil is also sent for cracking using hydrogen in a 'hydrocracking unit' to produce smaller chain hydrocarbons.
